

**Safety of proteins –
lessons from non-clinical assessment
and in-silico prediction of immunogenicity
of therapeutic proteins**

Immunogenicity

propensity of a protein to trigger an immune response

beneficial
(vaccine)

unwanted
(therapeutic or food)

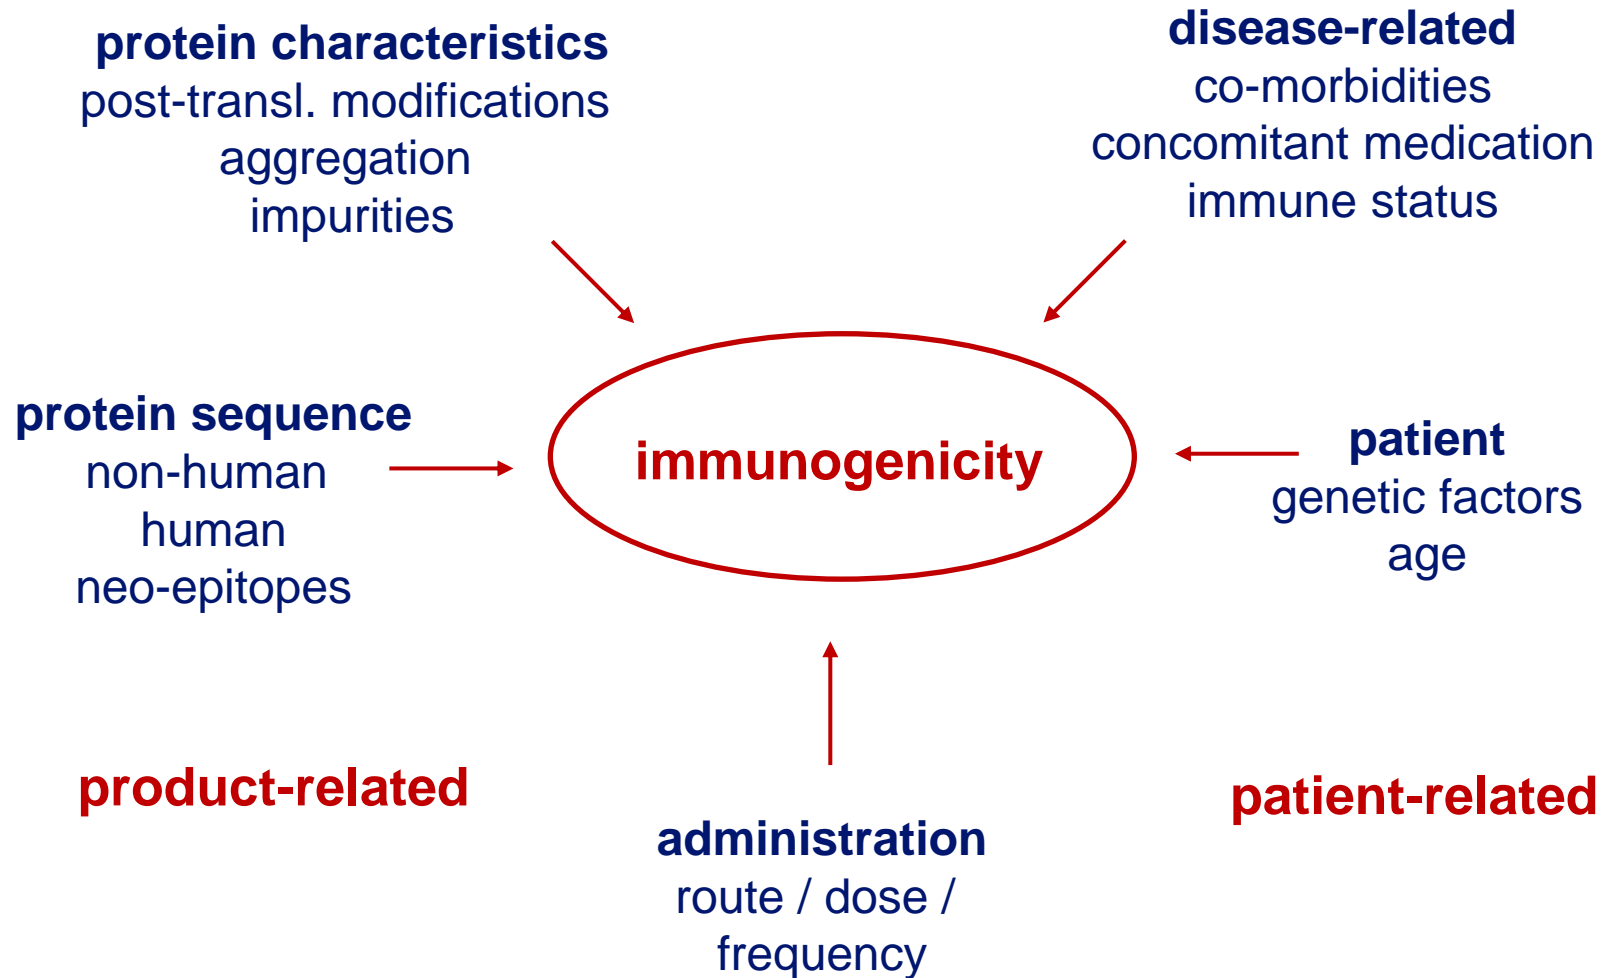

immune protection
against infectious
disease

immune-related adverse reactions
hypersensitivity / anaphylaxis

Factors influencing immunogenicity

Immunogenicity risk assessment

Multi-step approach

- in silico analyses
- in vitro / ex vivo assays
- combination with clinical data
- protein de-immunisation
(if feasible)

T cell-dependent B cell immune response

In silico screening

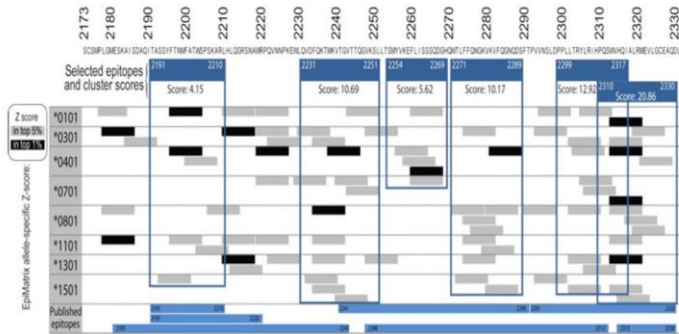

- **in silico** assessment of T cell epitopes based on protein sequence
 - predict binding of peptides to MHC II
 - identify epitopes recognised by effector T cells vs. regulatory T cells (*De Groot et al., Blood 2018*)
 - comparison of predictions with epitope data bases (e.g. www.iedb.org)
- **immunogenicity score / ranking**
- **de-immunisation:** modify protein sequence to remove T cell epitopes

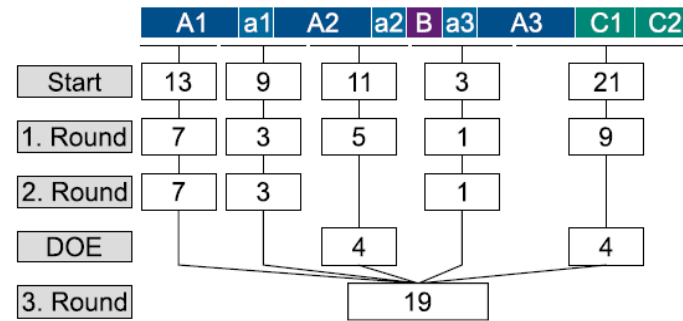

(epivax.com)

Case study - de-immunised coagulation factor VIII

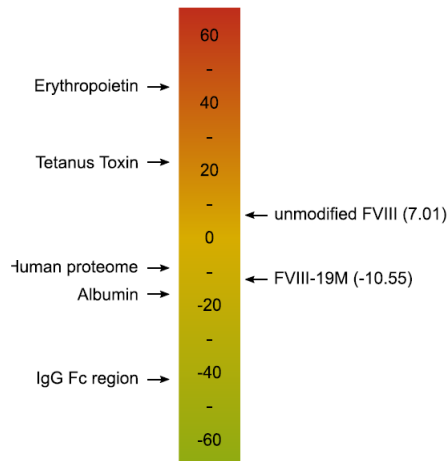

Predicted HLA II epitope map of FVIII C2 domain

Incorporation of aa substitutions in FVIII sequence

Immunogenicity scale

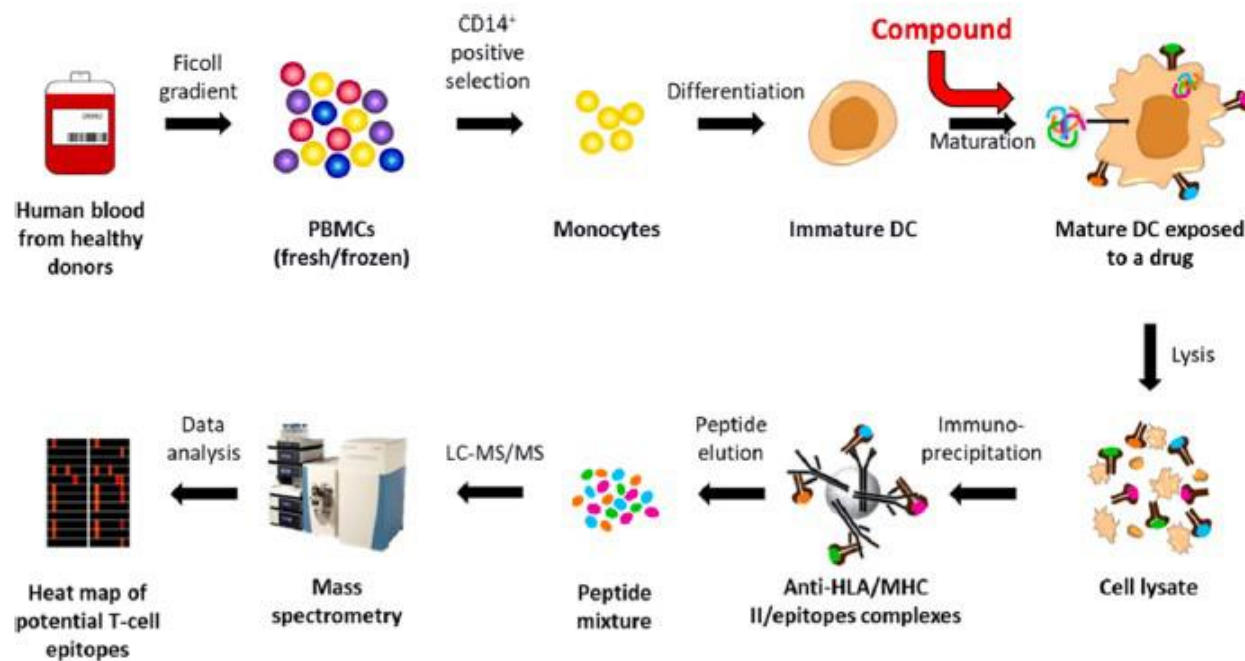

In vitro T cell response to modified FVIII

In vitro analysis of immunogenicity

MAPPs assay: MHC-associated peptide proteomics for identification of processed and presented epitopes

In vitro analysis of immunogenicity

Early / innate assays

ability to activate antigen-presenting cells

- DC activation / maturation assay
(can detect protein aggregation)
- cytokine release assay

T cell assays

assessment of T cell responses towards protein / epitope

- (CD8-depleted) PBMC
- DC-T cell assay
- peptide assay

In vitro assays - considerations

Benchmarking of in vitro assays

- use of **reference molecules** with known immunogenic potential (low, high)
- if feasible use **PBMC from same donor** for different assays e.g. T cell assay and MAPPs
- assess relationship of **in vitro results and clinical data** (once available)

Caveats

- results for one protein with different assays may not agree
- results from in vitro assays may not agree with clinical data

QSP approach to predict immunogenicity

- **Quantitative Systems Pharmacology**
 - combination of computational modelling and experimental data
 - integration of in vitro assay data and in silico model data with clinical data
- Mathematical model of immunogenicity of therapeutic proteins (theoretical model and application)
(Chen et al., 2014, CPT Pharmacometrics Syst. Pharmacol.)
- Certara / Pharma consortium (established in 2017) development of **Immunogenicity Simulator**
 - prediction of ADA incidence
 - prediction of impact on PK and on PD

IG Simulator

Input data

Bioinformatics

- T-cell epitopes
- MHC II binding
- Isoelectric point
- Hydrodynamic radius

In-vitro Assays

- T-cell proliferation
- Antigenic peptide
- MHC II binding
- DC activation

Population data

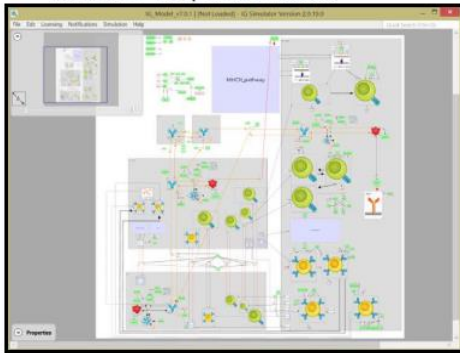

- PBPK parameters
- HLA allele frequencies
- Immune system baselines

Clinical data

- Compound PK
- ADA titers
- Adverse events

IG Simulator

Immune response model

Simcyp Biologics PBPK model

Epitope ID	Gene	Epitope 1 Binding Constant (week)	Epitope 2 Binding Constant (week)
0301*16:01	DQB1	83	527
0301*16:03	DQB1	83.76	34.37
0301*16:04	DQB1	125	25.33
0301*16:07	DQB1	85.15	69.44
0301*16:10	DQB1	33.29	47.87
0301*16:13	DQB1	89	11.82
0301*16:02	DQB1	304	104.87
0301*16:11	DQB1	74.95	4300
0301*16:05	DQB1	271.20	193.20
0301*16:06	DQB1	34.4	4000
0301*16:01	DQB1	96.47	4000
Non of DQB	DQB1	4000	4000
DQA	DQA	4000	4000
DPA	DPA	4000	4000

QSP approach - considerations

- **baseline assumption:**
T cell epitopes play pivotal role in B cell-driven ADA response
- multiple in silico / in vitro methods can be used
 - each method must be carefully implemented
 - characterisation of assay performance parameters
 - use of benchmarking molecules
- integrate data from several orthogonal methods
- **limitation:**
knowledge of patient-related factors influencing the development of ADA

Prediction of **food immunogenicity** ?

Likely feasible, but would require modification of the models

- known food allergens are proteins
in food: mixtures of proteins / substances
→ which protein exactly is the antigen / allergen ?
- oral uptake and digestion (protein cleavage and modification)
→ which peptide is available to the immune system ?
- specific characteristics of mucosal immune system, IgE responses
- **scientific challenge**: knowledge of processes inducing the immunogenic / allergenic response
- **regulatory challenge**: model validation for use in risk assessment

Thanks for your attention.
